

## Truss Problem 1 - Forces on and in a truss (Method of Joints)

This truss problem was posted in a math group on Facebook. (By a tutor, although they may only tutor standard high school math and presumably not mechanics or physcis.)

It does not specify a method and since we want all of the internal forces I am using the <u>Method</u> <u>of Joints</u>. First we calculate the external reaction forces at A and C, treating the structure as a single object in static equilibrium. Then each joint is anayzed separately by summing the x-force components and the y-force components and setting those to zero (for static equilibrium).

There is another approach – the <u>Method of Sections</u>. In that method the truss is cut into parts and each part is treated as a complete body. If it is "cut" vertically between C and D we just consider the reaction force at C and the internal forces in DC and BC, treating all of them as external forces on that section. This method is useful if we only need the forces in a few certain elements. In a video walk-through I cover this but only briefly. At least one other problem is done that way as specified. (See Truss Problem IV.)

As a final comment it is possible to immediately see that AB is a zero-force element. At A it is perpendicular to the other two forces. Those are in the y direction and AB is along the x axis. A force sum in the x direction equal to zero immediately shows that AB must have zero force.
